Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] scenario_label: Human-readable scenario name used in charts and summary tables.
[4] year: Model year index from genesis (0..250).
[5] end_height: Inclusive ending block height for the row interval.
[6] burn_active: 1 means tail-era burn rules apply for that sampled year; 0 means burn is inactive.
[7] capacity_pct: Assumed policy-budget utilization level for the scenario, as percent of max block vbytes.
[8] reward_per_block_atho: Consensus block subsidy active at sampled height (ATHO/block).
[9] annual_issuance_atho: Coins newly minted during the sampled year (ATHO/year).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_fees_total_atho: Total fee pool under assumed utilization at fee floor (ATHO/year).
[4] annual_burn_atho: Coins permanently removed from fees under burn policy (ATHO/year).
[5] annual_miner_fees_atho: Fee share retained by miners after burn split (ATHO/year).
[6] annual_miner_revenue_atho: Miner income = annual issuance + miner fee share (ATHO/year).
[7] cumulative_emitted_atho: Total minted coins from genesis through sampled year-end (ATHO).
[8] cumulative_burned_atho: Total burned fees from genesis through sampled year-end (ATHO).
[9] circulating_supply_atho: Circulating = cumulative emitted - cumulative burned (ATHO).
[10] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.

Footnotes

[1] Rows: Each row is one (scenario, year) sample from the yearly simulator output.
[2] scenario_key: Stable machine key for joining rows across CSV exports and scenarios.
[3] annual_net_change_atho: Year-over-year circulating supply change after burn (ATHO/year).
[4] annual_net_rate_pct: Annual net supply change divided by previous circulating supply (%/year).
[5] tx_per_block_est: Estimated transactions per block at average tx size and scenario utilization.
[6] tps_est: Estimated transactions per second from tx/block and 120-second blocks.
[7] All ATHO values are deterministic model outputs aligned to current consensus constants.
